

Genetic programming

Genetic programming is a biology inspired method. There is a population of solution candidates, which is improved with each successive generation. Next generation is created from the previous one by applying crossing over and mutations.

1. Write a program solving the set partition problem using genetic programming. It is important to use an optimization version of this problem, since genetic programming has to have some way to rate the solutions in order to improve them.
2. Test different ways of selection, for example elitism or weighted probability.
3. Try to solve the TSP problem that way. Cross over of permutations requires some additional technique, for example the order crossover.
